

Note that there is potential to go a step further. We should be able to estimate from existing data the amount of efficiency loss for a given increase in intake pressure drop. This would enable the calculation of extra fuel cost, thereby supporting an economically driven decision on filter cleaning/replacement.

**SUMMARY AND CONCLUSIONS:**

Properly applied and selectively applied, the condition monitoring programs that have been described here can return benefits well beyond the cost of the programs. There is a substantial amount of experience and judgement involved; the programs are not automatic, nor are they "pure science".

Experienced specialists should be involved in the design, implementation and execution of condition monitoring programs.
